Abstract

This document contains notes about neural network regarding the Temporal Differential reinforcement alghorithms.

1 General

Let us have a neural network composed by N layers. Each layer i=1...N is composed by s_i neurons.

The first layer

$$H_{1i} = x_i$$

rappresents the input values of the network. We identify the input bias signals with

$$H_{i0}=1$$

Each neuron processes the input signals from its layer and produces the output signal to the next layer.

Let us exam a NLR (Non Linear regression) network.

The transfer function of each hidden neuron i < N is

$$H_{(i+1)j} = \frac{1}{1 + e^{-Z_{ij}}}$$

$$Z_{ij} = \sum_{k=0}^{s_i} w_{ijk} H_{ik}$$
(1)

the transfer function of each output neuron N is

$$H_{Nj} = \sum_{k=0}^{s_{N-1}} w_{(N-1)jk} H_{(N-1)k}$$
 (2)

2 Cost Function

Let y_j be the expected output for the neuron j, the error of neuron is

$$\delta_{(N-1)j} = y_j - H_{Nj} \tag{3}$$

The cost function of the network is

$$J = \begin{vmatrix} \frac{1-\alpha}{2} \sum_{i=1}^{s_N} \delta_{(N-1)i}^2 + \frac{\alpha}{2} \sum_{i,j,k} w_{ijk}^2, & k \ge 1 \\ \frac{1-\alpha}{2} \sum_{i=1}^{s_N} \delta_{(N-1)i}^2, & k = 0 \end{vmatrix}$$

where α is the regularization factor.

Let us extract ∇J

$$\frac{\partial}{\partial w_{ijk}}J = \left| \begin{array}{c} (1-\alpha)\sum_{r=1}^{s_N} \delta_{(N-1)r} \frac{\partial}{\partial w_{ijk}} \delta_{(N-1)r} + \alpha w_{ijk}, \ k \geq 1 \\ (1-\alpha)\sum_{r=1}^{s_N} \delta_{(N-1)r} \frac{\partial}{\partial w_{ijk}} \delta_{(N-1)r}, \ k = 0 \end{array} \right|$$

By (3) we have

$$\frac{\partial}{\partial w_{ijk}}\delta_{(N-1)r} = -\frac{\partial}{\partial w_{ijk}}H_{Nr}$$

therefore

$$\frac{\partial}{\partial w_{ijk}}J = \begin{vmatrix} -(1-\alpha)\sum_{r=1}^{s_N} \delta_{(N-1)r} \frac{\partial}{\partial w_{ijk}} H_{Nr} + \alpha w_{ijk}, & k \ge 1 \\ -(1-\alpha)\sum_{r=1}^{s_N} \delta_{(N-1)r} \frac{\partial}{\partial w_{ijk}} H_{Nr}, & k = 0 \end{vmatrix}$$

By now we disregard the regularization effects.

By (2) we have

$$\frac{\partial}{\partial w_{(N-1)jk}} H_{Nj} = H_{(N-1)k}$$
$$\frac{\partial}{\partial w_{(N-1)jk}} H_{Nr} = 0, \ r \neq j$$

therefore

$$\frac{\partial}{\partial w_{(N-1)jk}}J = -\delta_{(N-1)j}H_{(N-1)k}$$

By (2) and $i \leq N-2$ we have

$$\frac{\partial J}{\partial w_{ijk}} = -\sum_{r} \delta_{(N-1)r} \frac{\partial}{\partial w_{ijk}} \left[\sum_{s} w_{(N-1)rs} H_{(N-1)s} \right] =$$

$$= -\sum_{r,s} \delta_{(N-1)r} w_{(N-1)rs} \frac{\partial}{\partial w_{ijk}} H_{(N-1)s}$$

By (1) we have

$$\frac{\partial}{\partial w_{ijk}} H_{(i+1)j} = \frac{\partial}{\partial Z_{ij}} H_{(i+1)j} \frac{\partial}{\partial w_{ijk}} Z_{ij} = H_{(i+1)j} (1 - H_{(i+1)j}) Hik$$

therefore

$$\frac{\partial}{\partial w_{(N-2)jk}}J = -\sum_r \delta_{(N-1)r} w_{(N-1)rj} H_{(N-1)j} (1 - H_{(N-1)j}) H_{(N-2)k}$$

3 Back-propagation

Let us define

$$\delta_{(N-2)j} = \sum_{r} \delta_{(N-1)r} w_{(N-1)rj} H_{(N-1)j} (1 - H_{(N-1)j})$$

Then we have

$$\frac{\partial}{\partial w_{(N-2)jk}}J = -\delta_{(N-2)j}H_{(N-2)k}$$

We can induce just for $i \leq N-2$

$$\delta_{ij} = \sum_{k} \delta_{(i+1)k} w_{(i+1)kj} H_{(i+1)j} (1 - H_{(i+1)j})$$

while in general

$$\frac{\partial}{\partial w_{ijk}}J = -\delta_{ij}H_{ik}$$

Let us now define the back-propagation tensor as

$$B_{ijk} = w_{(i+1)kj}H_{(i+1)j}(1 - H_{(i+1)j}), \ i \le N - 2$$

The errors on intermediate layers are

$$\delta_{ij} = \sum_{k=1}^{s_i} \delta_{(i+1)k} B_{ijk}, \ i = 1 \dots N - 2$$

Now reintroducing the regularization effects we have

$$\frac{\partial}{\partial w_{ijk}} J = \begin{vmatrix} -(1-\alpha)\delta_{ij}H_{ik} + \alpha w_{ijk}, & k \ge 1\\ -(1-\alpha)\delta_{ij}H_{ik}, & k = 0 \end{vmatrix}$$

The weight changes to reduce the error (gradient descent) are

$$\Delta w_{ijk} = -\eta \frac{\partial}{\partial w_{ijk}} J = \begin{vmatrix} \eta \left[(1 - \alpha) \delta_{ij} H_{ik} - \alpha w_{ijk} \right], & k \ge 1 \\ \eta (1 - \alpha) \delta_{ij} H_{ik}, & k = 0 \end{vmatrix}$$

where η is the learning rate.

4 Returns

Let us have a process where the best policy generates a never end episode (infinite length) and let the positive reward be $r_+ > 0$ every n steps, while a wrong choice ad step n generates the end of episode with a negative reward of $r_- < 0$.

The return at step n is then

$$R_{+} = \frac{r_{+}}{1 - \lambda^{2(n-1)}}$$

if the best strategy is applied otherwise

$$R_- = r_-$$

Suppose $R_+ \gg -R_-$ we have

$$\frac{r_+}{1-\lambda^{2(n-1)}} \gg -r_-$$

$$r_{+} \gg -(1 - \lambda^{2(n-1)})r_{-}$$

For example if $\lambda^{2(n-1)} = \frac{1}{2}, r_{-} = -1$ we have

$$r_+\gg \frac{1}{2}$$

such as $r_+ = 5$
